EP 0 741 465 B1

Description

[0001] The present invention relates to a transmission diversity system used in a mobile radio communication system for communication between a base station and a mobile station to perform diversity transmission from the base station to the mobile station.

[0002] In a conventional mobile radio communication system, the reception state (reception sensible state) of a transmission radio wave from a base station changes in a vehicle mobile station upon fading during the travel of the vehicle mobile station.

[0003] The reception field strength at the mobile station changes due to interference caused by a difference between radio wave propagation paths upon reflection or diffraction of the radio wave at a mountain or the like. That is, fading occurs. Multiple radio wave propagation (multi-path) occurs due to irregular reflection at a building in a city. In this case, the period is short and deep fading tends to occur. As a countermeasure for this, an antenna diversity reception system is used.

[0004] In this antenna diversity reception system, a signal having the highest field strength is selected from all the reception signals from a plurality of antennas having less correlation. In this case, the plurality of antennas are spaced apart from each other to obtain a low correlation level, and cables are connected to these antennas. That is, the apparatus becomes bulky at high cost. In particular, it is difficult to employ this system to a compact portable telephone carried by a user.

[0005] A technique as an improved technique of the above antenna diversity reception system is described in Japanese Patent Laid-Open No. 5-29992 in which transmission is performed from a base station in a transmission diversity so as to obtain the same effect as that of a reception diversity.

[0006] Fig. 4 shows the arrangement of this transmission diversity system.

[0007] Referring to Fig. 4, the transmission frequency is equal to the reception frequency in this example, and TDD (Time Division Duplex) can be applied as a transmission scheme between a base station and a mobile station. In a reception time slot, an antenna 155a is connected to a receiver 152a, and an antenna 155b is connected to a receiver 152b under the control of a switch control circuit 153. A signal transmitted from a mobile station and received by the receiver 152a is decoded by a decoder 156a, and its error is detected by an error detection circuit 111a.

[0008] Similarly, a signal transmitted from the mobile station and received by the receiver 152b is decoded by a decoder 156b, and its error is detected by an error detection circuit 111b. An error bit number comparator circuit 112 identifies one of reception paths (i.e., one of signals from the antennas 155a and 155b) which has a smaller number of errors in accordance with the number of bits output from the error detection circuits 111a and 111b for the respective reception paths, and this identification result is stored in a storage circuit 159.

fication result is stored in a storage circuit 159.

[0009] At the same time, a baseband switch 158 selects a reception data signal from the reception path having a smaller number of errors on the basis of this identification result and outputs the reception data signal to the next stage. In this manner, diversity reception is performed in the base station.

[0010] In a transmission time slot, a high frequency switch 154 is controlled by the switch control circuit 153 on the basis of the reception path information stored in the storage circuit 159. One of the signals (reception paths) from the antennas 155a and 155b which has a smaller number of errors in reception is connected to a transmitter 151 under the control of the switch control circuit 153, and the other one of the signals from the antennas 155a and 155b is grounded. Therefore, diversity transmission can be performed.

[0011] In this case, an antenna selected at the time of reception obtains optimal pattern characteristics also in transmission. In addition, this reception/transmission time slot has a short period of time, so that a multipath (fading) during this period of time can be neglected. Although the above scheme can be applied to a PHP (Personal Handy-Phone system), it cannot be applied when the transmission frequency is different from the reception frequency. In addition, no effect can be expected for fading having a period shorter than that of the transmission/reception interval (time slot).

[0012] Another technique of this type described in Japanese Patent Laid-Open No. 2-200018 is known.

[0013] Figs. 5A and 5B show the arrangements of a base station and a mobile station, respectively.

[0014] Fig. 5A shows a base station a for transmitting data and Fig. 5B shows a mobile station b for receiving the data. Through a control part 211, an identifier adding part 210, and a baseband generating part 205, the base station a adds, to the first packet, a branch identifier representing a radio transmission system (radio transmission line: branch) for transmitting the first packet. The base station a transmits data through a modulator 206, a transmitter 207, a switch 208, and one branch of antennas 209a and 209b. Another branch is selected for the second packet, and its branch identifier is added to the second packet. The resultant packet data is transmitted.

[0015] On the other hand, in the mobile station b, a packet transmitted from another branch is received through an antenna 229 and a receiver 230. The reception level is detected by a level detecting part 225. If a reception level is high, the corresponding branch is stored in a storing part 224. A branch identifier discriminated through a demodulator 228, a baseband generating part 227, and an identifier detecting part 226 is stored in the storing part 224. Transmission is performed from an identifier adding part 223 through a baseband generating part 219, a modulator 220, a transmitter 221, and an antenna 222.

[0016] A signal transmitted from the mobile station b

is received through one of antennas 218a and 218b, a switch 217, and a receiver 216. This transmission level (field strength) is detected by a level detecting part 212. At the same time, a branch identifier is discriminated through a demodulator 215, a baseband generating part 214, and an identifier deciding part 213. The discriminated branch identifier 211 is supplied, and one of the antennas 209a and 209b is selected on the basis of the branch identifier.

[0017] As described above, the mobile station decides the optimal branch. The decision result is notified to the base station a, and the base station a selects an optimal antenna, thereby performing diversity transmission. EP0479741 discloses such a system. Tail bits are used for identification of the antenna that is to be activated. The mobile station signals the antenna selection and the base station selects the best antenna with a switch.

[0018] Figs. 6A to 6C show the format of a radio channel to which the TDMA (Time Division Multiple Access) or FDD scheme is applied.

[0019] Fig. 6A shows a frame structure, Fig. 6B shows a download link, and Fig. 6C shows an upload link. The frame structure has one TDMA frame, a control slot, communication slots, and a branch identifier B in the control slot.

[0020] The download link in one frame is constituted by a control slot and a communication slot. The upload link has a communication slot. A notification signal including the branch identifier is transmitted in the download link control slot every predetermined time interval to notify the mobile station of the base station information and the like. Every time this notification signal is transmitted, the transmission antenna is switched to the other. Every time the mobile station receives the notification signal, the mobile station detects the level of the reception field strength, and stores the detection result. This processing is repeated to determine the branch having a maximum field strength level.

[0021] The branch identifier selected in this determination is inserted in data, and the resultant data is transmitted. For example, in a communication slot C assigned to the mobile station, the mobile station transmits the selected identifier to the base station through the slot in the upload link. Upon reception of the selected branch identifier, the base station transmits the time slot assigned to the mobile station from the antenna based on the branch identifier. In this manner, the transmission antennas are switched every third frame, which frame interval is minimum.

[0022] In the prior arts described above, the former example cannot be applied when the transmission frequency is different from the reception frequency, and no effect is obtained in fading whose interval is shorter than the transmission/reception interval. The latter example can be applied even if the transmission frequency is different from the reception frequency. Since the latter method is based on packet transmission, the field

strength in the branch must be time-divisionally measured. For example, when the length of one TDMA frame is 8 ms, the shortest period capable of allowing field strength measurement is 16 ms which corresponds to a two-frame period, i.e., a frequency of about 60 Hz. This is not suitable for cellular diversity in which fading of 100 Hz tends to occur. In addition, since a mobile radio system for continuously transmitting data is also available, continuous, high-speed diversity transmission is desired.

[0023] The present invention has been made to solve the conventional drawbacks described above, and has as its object to provide a transmission diversity system capable of notifying a base station of optimal radio transmission system information obtained by causing a mobile station to measure an identification signal always transmitted from the base station, and of performing continuous, high-speed diversity transmission and stable reception at the mobile station in a CDMA (Code Division Multiple Access) scheme employing a spread spectrum modulation scheme.

[0024] In order to achieve the above object of the present invention, there is provided a transmission diversity system as it is set out by the appended claims for selecting one of a plurality of radio transmission systems in a base station to perform diversity transmission of data to a mobile station, wherein the base station adds transmission data and identification signals different in the plurality of radio transmission systems to transmit resultant radio signals from the plurality of radio transmission systems, and transmits transmission data from one radio transmission system based on optimal radio transmission system information transmitted as a radio wave from the mobile station, and the mobile station determines an identification signal representing an optimal reception state from the plurality of identification signals detected from the data received from the plurality of radio transmission systems of the base station and transmits the determined optimal radio transmission system information to the base station.

[0025] In the transmission diversity system having above arrangement, the base station transmits radio adds identification signals different in a plurality of radio transmission systems and transmission data multiplexed by the CDMA scheme and transmits radio signals respectively from the plurality of radio transmission systems. The mobile station detects a plurality of identification signals for the plurality of radio transmission systems from the data received from the base station and determines an identification signal representing an optimal reception state. The determined optimal radio transmission system information is transmitted to the base station. The base station transmits data from one radio transmission system based on the optimal radio transmission system information transmitted from the mobile station.

[0026] In this case, the base station transmits a plurality of types of identification signals different in the plu-

rality of radio transmission systems, and the mobile station transmits optimal radio transmission system information of one identification signal representing the optimal reception state.

[0027] The base station transmits a plurality of types of identification signals which are different in the plurality of radio transmission systems and are delayed from a reference identification signal, and the mobile station transmits optimal radio transmission system information on the basis of a delay profile representing the intensity distribution of identification signals with respect to the delay time upon calculation of a sliding function.

[0028] In this manner, the field strength of the identification signal always transmitted from the base station is measured by the mobile station, and the optimal radio transmission system information is notified to the base station on the basis of this measurement. As a result, continuous, high-speed diversity transmission can be performed in the CDMA employing the spread frequency modulation scheme.

Brief Description of the Drawings

Description of the Preferred Embodiment

[0030] Embodiments of transmission diversity systems according to the present invention will be described with reference to the accompanying drawings.

[0031] Fig. 1 shows the arrangement of a transmission diversity system according to the first embodiment.

[0032] The first embodiment shown in Fig. 1 mainly comprises a base station 1 having two branches (radio transmission systems) and a mobile station 2.

[0033] The base station 1 comprises a pilot signal generator 3 for generating a pilot signal A for identifying one of the two branches, and a pilot signal generator 4 for generating a pilot signal B for identifying the other of

the two branches. In addition, the base station 1 comprises an encoder 5 for encoding and outputting transmission data, an adder 6 for adding the pilot signal A and the encoded data, and an adder 8 for adding the pilot signal B and the encoded data.

[0034] The base station 1 also comprises attenuators (ATTs) 9 and 10 for attenuating the level of the encoded data from the encoder 5, a transmitter 11 and an antenna 13, both of which modulate the pilot signal A and the encoded data from the ATT 9, set a transmission frequency, and transmit the resultant data, and a transmitter 12 and an antenna 14, both of which modulate the pilot signal B and the encoded data from the ATT 10, set a transmission frequency, and output resultant data.

[0035] The base station 1 further comprises an antenna 15 for receiving a radio wave transmitted from the mobile station 2, a receiver 16 for receiving a signal from the antenna 15, performing high-frequency amplification, frequency conversion, and demodulation, and outputting a demodulated signal, and a decoder 17 for decoding the demodulated signal from the receiver 16 and outputting the reception data.

[0036] The mobile station 2 comprises an antenna 18 for receiving a radio wave from the base station 1, a receiver 19 for performing high-frequency amplification, frequency conversion, and demodulation of the signal received from the antenna 18, and a decoder 20 for decoding the demodulated signal from the receiver 19 and outputting the decoded data. The mobile station 2 also comprises a pilot signal level detector 21 for detecting the pilot signal A from the demodulated signal from the receiver 19 and the level (reception field strength) of this signal, and a pilot signal level detector 22 for detecting the pilot signal B from the demodulated signal from the receiver 19 and the level (reception field strength) of this signal.

[0037] The mobile station 2 further comprises a determination circuit 23 for comparing the pieces of level information of the pilot signals A and B from the pilot signal level detectors 21 and 22 and determining one of the pilot signals A and B which has a higher level, an encoder 24 for encoding transmission data, inserting branch information of the determination result into this encoded data, and outputting the resultant data, and a transmitter 25 and an antenna 26, both of which transmit the encoded data from the encoder 24 and the determination result to the base station 1.

[0038] The operation of the first embodiment will be described below.

[0039] The pilot signal A output from the pilot signal generator 3 is always transmitted through the adder 6, the transmitter 11, and the antenna 13. The pilot signal B output from the pilot signal generator 4 is always transmitted through the adder 8, the transmitter 12, and the antenna 14. Data to be transmitted to the mobile station 2 is input to the encoder 5, and the encoded data is output to the ATTs 9 and 10.

[0040] The encoded data from the ATT 9 is added (su-

perposed) by the adder 6, and the resultant data is transmitted from the transmitter 11 to the mobile station 2 through the antenna 13. The encoded data from the ATT 10 is added (superposed) by the adder 8, and the resultant data is transmitted from the transmitter 8 to the mobile station 2 through the antenna 14. The radio wave from the base station 1 is received by the antenna 18 of the mobile station 2 and is input to the receiver 19. The receiver 19 performs high-frequency amplification, frequency conversion, and demodulation. Data received from the base station 1 and decoded from the demodulated signal by the decoder 20 is output.

[0041] The demodulated signal output from the receiver 19 is input to the pilot signal level detector 21 to detect the pilot signal A, and its level (reception field strength) is detected. At the same time, the demodulated signal output from the receiver 19 is input to the pilot signal level detector 22 to detect the pilot signal B, and its level (reception field strength) is detected.

[0042] The pieces of level information of the pilot signals A and B which are detected by the pilot signal level detectors 21 and 22 are input to the determination circuit 23. The determination circuit 23 compares the pieces of input level information to determine that the pilot signal A or B has a higher level. In other words, transmission of one of the branches which has a higher field strength is determined. The optimal branch information of the determination result is output to the encoding circuit 24. The encoding circuit 24 encodes the transmission data, inserts the optimal branch information in the encoded data, and transmits the resultant data from the transmitter 25 to the base station 1 through the antenna 26.

[0043] The radio wave from the mobile station 2 is received by the receiver 16 through the antenna 15 of the base station 1, and the demodulated signal from the receiver 16 is input to the decoder 17. The data transmitted from the base station 1 is decoded by the decoder 17, and at the same time the optimal branch information is extracted. This optimal branch information changes the gains of the ATTs 9 and 10.

[0044] When the branch of the pilot signal A represents the optimal branch information, the gain of the ATT 10 is set to, e.g., -30 dB, and no attenuation is performed in the ATT 9. Transmission of the encoded data from the branch (the transmitter 12 and the antenna 14) of the pilot signal B is stopped, and the encoded data from the branch (the transmitter 11 and the antenna 13) of the pilot signal A is transmitted.

[0045] When the branch of the pilot signal B represents optimal branch information, an operation reverse to the above operation is performed. That is, the gain of the ATT 9 is set to, e.g., -30 dB, and transmission of the encoded data from the branch of the pilot signal A is stopped.

[0046] As described above, the optimal branch information having a good reception state is identified in the mobile station 2, and this optimal branch information is transmitted to the base station 1. The data is transmitted

from the branch selected by the base station 1 on the basis of the optimal branch information. For this reason, continuous, high-speed diversity transmission is performed, and stable deception is allowed in the mobile station 2.

[0047] Fig. 2 shows the arrangement of the second embodiment.

[0048] The second embodiment shown in Fig. 2 has a base station 1 having two branches and a mobile station 2, as in the first embodiment. The base station 1 comprises a pilot signal generator 3 for generating a pilot signal A, an encoder 5, adders 6 and 8, ATTs 9 and 10, transmitters 11 and 12, antennas 13, 14, and 15, a receiver 16, and a decoder 17.

[0049] A delay circuit 27 for delaying the pilot signal A output from the pilot signal generator 3 as the second embodiment to output a pilot signal Ba to the adder 8 is arranged.

[0050] The mobile station 2 comprises an antenna 18, a receiver 19, a decoder 20, a determination circuit 23, an encoder 24, a transmitter 25, and an antenna 26. The mobile station 2 also comprises a search circuit 28 for searching and identifying the pilot signals A and Ba as the second embodiment, and detecting the levels of the pilot signals A and Ba.

[0051] The operation of the second embodiment will be described below.

[0052] The pilot signal A output from the pilot signal generator 3 is input to the adder 6 and the delay circuit 27. The delay circuit 27 delays the pilot signal A by a time T to output the pilot signal Ba to the adder 8. As in the first embodiment, the encoded data output from the encoder 5 is input to the adders 6 and 8 through the ATTs 9 and 10 and added to the pilot signals A and Ba. The resultant signals are transmitted from the transmitters 11 and 12 and the antennas 13 and 14.

[0053] As in the first embodiment, the mobile station 2 performs processing in the antenna 18, the receiver 19, and the decoder 20. The demodulated signal from the receiver 19 is input to the search circuit 28. The search circuit 28 searches and identifies the pilot signals A and Ba and detects the levels of the pilot signals A and Ba.

[0054] Fig. 3 explains the identification and level states of the pilot signals A and Ba in the search circuit 28.

[0055] Referring to Figs. 2 and 3, the search circuit 28 uses a correlator for calculating a sliding function between the pilot signal A and a reception signal. The delay profile representing the levels (field strength values) of the pilot signals A and Ba with respect to the delay time is obtained from the correlation calculation result, as shown in Fig. 3.

[0056] Referring to Fig. 3, a time D is a delay time for radio wave propagation between the base station 1 and the mobile station 2, and a time T is a time between the pilot signal A and the pilot signal Ba obtained by delaying the pilot signal A by the delay circuit 27. Since the time

T is known in advance, the capture of the pilot signal A allows identification of the pilot signal Ba present during the time T. In this case, when the pilot signals A and Ba of maximum levels are detected, and other pilot signals Aa, Ab, Baa, and Bab are not detected, subsequent de-

termination can be facilitated.

[0057] The determination circuit 23 determines one of the pilot signals A and Ba which has a higher level. In other words, transmission from one of the branches which has a higher field strength is determined. The optimal branch information of the determination result is transmitted to the base station 1 through the encoder 24, the transmitter 25, and the antenna 26. Subsequent processing in the base station is identical to that of the first embodiment.

[0058] Even in the second embodiment, continuous, high-speed diversity transmission is performed, and stable reception is performed in the mobile station 2 as in the first embodiment.

[0059] As can be apparent from the above description, according to a transmission diversity system of the present invention, a base station adds data to be transmitted and a plurality of types of identification signals different in a plurality of radio transmission systems (branches) and transmits the resultant data from the plurality of radio transmission systems. A mobile station determines an identification signal from a radio transmission system representing an optimal reception state from the data received from the base station and transmits the determined optimal radio transmission system information to the base station. Since data is transmitted from one radio transmission system in the base station is transmitted on the basis of this information, continuous, high-speed diversity transmission can be performed, and stable reception can be performed at the mobile station in the CDMA scheme employing the spread spectrum modulation scheme.

Claims

1. A transmission diversity system including a base station (2) and a mobile station (2), the base station comprising a plurality of radio transmission systems (11, 13; 12, 14) and performing diversity transmission of data to said mobile station (2),
 where said base station (1) comprises means for adding transmission data and identification signals (A, B; A, Ba) different in the plurality of radio transmission systems to transmit resultant radio signals from said plurality of radio transmission systems (11, 13; 12, 14), and levels of said transmission data from said plurality of radio **characterized in that** it further comprises means for controlling transmission systems based on optimal radio transmission system information transmitted as a radio wave from said mobile station (2), and
 said mobile station (2) comprising means for

determining an identification signal representing an optimal reception state from the plurality of identification signals (A, B; A, Ba) detected from the data received from the plurality of radio transmission systems (11, 13; 12, 14) of said base station (1) and means for transmitting the determined optimal radio transmission system information to said base station (1).

2. A system according to claim 1, wherein
 said base station (1) comprises
 identification signal generation means (3, 4) for generating the plurality of types of identification signals (A, B) different in the plurality of radio transmission systems (11, 13; 12, 14),
 setting means (9, 10) for setting different levels between transmission data of said plurality of radio transmission systems (11, 13; 12, 14),
 addition means (6, 8) for adding the identification signals (A, B) from said identification signal generation means (3, 4) and the data output from said setting means (9, 10) and outputting resultant addition data,
 base station radio transmitting means (11, 12) for transmitting the radio addition data respectively output from said addition means (6, 8), and
 base station radio reception/extraction means (16, 17) for receiving radio transmission from said mobile station (2) and extracting the optimal radio transmission system information representing transmission through the optimal radio transmission system determined by said mobile station (2), wherein said setting means selects said optimal transmission system by setting said different levels based on the optimal radio transmission system information extracted by said base station radio reception/extraction means (16, 17); and
 said mobile station (2) comprises
 mobile station radio reception means (19) for outputting data received from said base station (1),
 identification signal detection means (21, 22) for detecting the plurality of identification signals (A, B) different in said plurality of radio transmission systems (11, 13; 12, 14) from data received by said mobile station radio reception means (19),
 determination means (23) for determining one of the plurality of identification signals detected by said identification signal detection means (21, 22), and
 mobile station radio transmission means (25) for transmitting the optimal radio transmission system information representing a radio transmission system of said base station which transmits the identification signal determined by said determination means (23).
3. A system according to claim 1, wherein
 said base station (1) comprises

identification signal generation means (3) for generating one identification signal (A),

delay means (27) for delaying the identification signal (A) from said identification signal generation means (3);

setting means (9, 10) for setting different levels between transmission data of said plurality of radio transmission systems (11, 13; 12, 14),

addition means (6, 8) for adding data output from said setting means (9, 10) and the identification signal (A, Ba) from said identification signal generation means (3) or said delay means (27) and outputting resultant addition data,

base station radio transmission means (11, 12) for transmitting the radio addition data respectively output from said addition means (6, 8); and

base station radio reception/extraction means (16, 17) for receiving radio transmission from said mobile station (2) and extracting optimal radio transmission system information representing transmission through the optimal radio transmission system determined by said mobile station (2), wherein said setting means selects said optimal radio transmission system by setting said different levels based on the optimal radio transmission system information extracted by said base station radio reception/extraction means (16, 17); and

said mobile station (2) comprises

mobile station radio reception means (19) for outputting data received from said base station (1),

identification signal detection means (28) for detecting the plurality of identification signals (A, Ba) of said plurality of radio transmission systems (11, 13; 12, 14) from the data received from said mobile station radio reception means (19),

determination means (23) for determining one of the plurality of identification signals which is detected by said identification signal detection means (28) and represents an optimal reception state, and

mobile station radio transmission means (25) for transmitting the optimal radio transmission system information representing a radio transmission system of said base station (1) which transmits the identification signal determined by said determination means (23).

4. A system according to claim 3, wherein said identification signal detection means (28) comprises:

identification signal search means (28) for calculating a sliding function between a reception signal and the identification signal (A) serving as a reference from said identification signal generation means (3) and obtaining a delay profile representing field strengths of the identification signals with respect to a delay time; and

determination means (23) for obtaining the optimal radio transmission system information representing one of the plurality of identification signals

which has a highest signal strength from the delay profile obtained by said identification signal search means (28).

5. A system according to any of claims 2 to 4, wherein said setting means (9, 10) comprises a plurality of variable attenuation means (9, 10) for variably attenuating the transmission data for the respective radio transmission systems.

6. A system according to any of claims 2 to 4, wherein said setting means (9, 10) comprises switches for setting transmission or non-transmission of the transmission data for the respective radio transmission systems (11, 13; 12, 14).

7. A system according to any of claims 2 to 6, further comprising multiplexing means (5) for encoding a plurality of transmission data for a plurality of mobile stations (2) and outputting encoded data to said setting means (9, 10).

8. A system according to claim 7, wherein said multiplexing means (5) employs a CDMA (Code Division Multiple Access) scheme as a multiplexing scheme.

9. A base station in a transmission diversity system including a plurality of radio transmission systems (11, 13; 12, 14) and performing diversity transmission of data to a mobile station (2),

said base station (1) comprises means for adding transmission data and identification signals (A, B; A, Ba) different in the plurality of radio transmission systems to transmit resultant radio signals from said plurality of radio transmission systems (11, 13; 12, 14), and levels of said transmission data from said plurality of radio **characterized in that** it further comprises means for controlling transmission system based on optimal radio transmission system information transmitted as a radio wave from said mobile station (2), said optimal radio transmission system information generated by said mobile station (2) from the plurality of identification signals (A, B; A, Ba).

10. A base station according to claim 9, wherein

said base station (1) comprises

identification signal generation means (3, 4)

for generating the plurality of types of identification signals (A, B) different in the plurality of radio transmission systems (11, 13; 12, 14),

setting means (9, 10) for setting different levels between transmission data of said plurality of radio transmission systems (11, 13; 12, 14),

addition means (6, 8) for adding the identification signals (A, B) from said identification signal generation means (3, 4) and the data output from said setting means (9, 10) and outputting resultant

addition data,

base station radio transmitting means (11, 12)
for transmitting the radio addition data respectively
output from said addition means (6, 8), and

base station radio reception/extraction means 5
(16, 17) for receiving radio transmission from said
mobile station (2) and extracting the optimal radio
transmission system information representing
transmission through the optimal radio transmis- 10
sion system determined by said mobile station (2),
wherein said setting means selects said optimal ra-
dio transmission system by setting said different
levels based on the optimal radio transmission sys-
tem information extracted by said base station radio 15
reception/extraction means (16, 17).

Patentansprüche

1. Sendediversitätssystem mit einer Basisstation (1) 20
und einer Mobilstation (2), wobei die Basisstation
mehrere Funkübertragungssysteme (11, 13; 12, 14)
aufweist und eine Diversitätsübertragung von Da-
ten zur Mobilstation (2) ausführt;
wobei die Basisstation (1) eine Einrichtung 25
zum Addieren von Sendedaten und Identifizie-
rungssignalen (A, B; A, Ba), die für die mehreren
Funkübertragungssysteme verschieden sind, zum
Übertragen von von den mehreren Funkübertra- 30
gungssystemen (11, 13; 12, 14) erhaltenen Funk-
signale aufweist; und
dadurch gekennzeichnet, daß das System
ferner eine Einrichtung zum Steuern von Pegeln der
Sendedaten von den mehreren Funkübertragungs- 35
systemen basierend auf einer ein optimales Funk-
übertragungssystem anzeigenden Information auf-
weist, die als Funkwelle von der Mobilstation (2)
übertragen wird; und
die Mobilstation (2) aufweist: eine Einrichtung 40
zum Bestimmen eines einen optimalen Empfangs-
zustand anzeigenden Identifizierungssignals von
den mehreren Identifizierungssignalen (A, B; A,
Ba), die von den von den mehreren Funkübertra- 45
gungssystemen (11, 13; 12, 14) der Basisstation (1)
empfangenen Daten erfaßt werden, und eine Ein-
richtung zum Übertragen der ein optimales Funk-
übertragungssystem anzeigenden Information an
die Basisstation (1).
2. System nach Anspruch 1, wobei die Basisstation 50
aufweist:
eine Identifizierungssignalerzeugungseinrich-
tung (3, 4) zum Erzeugen der mehreren Typen
von Identifizierungssignalen (A, B), die für die 55
mehreren Funkübertragungssysteme (11, 13;
12, 14) verschieden sind;
eine Setzeinrichtung (9, 10) zum Setzen ver-

schiedener Pegel zwischen Sendedaten der
mehreren Funkübertragungssysteme (11, 13;
12, 14);

eine Addiereinrichtung (6, 8) zum Addieren der
Identifizierungssignale (A, B) von der
Identifizierungssignalerzeugungseinrichtung
(3, 4) und der von der Setzeinrichtung (9, 10)
ausgegebenen Daten und zum Ausgeben der
erhaltenen addierten Daten;

eine Basisstation-Funkübertragungseinrich-
tung (11, 12) zum Übertragen der von der Ad-
diereinrichtung (6, 8) jeweils ausgegebenen
addierten Funkdaten; und

eine Basisstation-Funkempfangs- und Extrak-
tionseinrichtung (16, 17) zum Empfangen eines
Funksignals von der Mobilstation (2) und zum
Extrahieren der ein optimales Funkübertra-
gungssystem anzeigenden Information, die ei-
ne Übertragung über das durch die Mobilstati-
on (2) bestimmte optimale Funkübertragungs-
system darstellt;

wobei die Setzeinrichtung das optimale Über-
tragungssystem durch Setzen der verschiedenen
Pegel basierend auf der das optimale Funkübertra-
gungssystem anzeigenden Information auswählt,
die durch die Basisstation-Funkempfangs- und Ex-
traktionseinrichtung (16, 17) extrahiert wurde; und
wobei die Mobilstation (2) aufweist:

eine Mobilstation-Funkempfangseinrichtung
(19) zum Ausgeben von von der Basisstation
(1) empfangenen Daten;

eine Identifizierungssignalerfassungseinrich-
tung (21, 22) zum Erfassen der mehreren Identi-
fizierungssignale (A, B), die für die mehreren
Funkübertragungssysteme (11, 13; 12, 14) ver-
schieden sind, von durch die Mobilstation-Funk-
empfangseinrichtung (19) empfangenen Daten;

eine Entscheidungseinrichtung (23) zum Be-
stimmen eines der mehreren Identifizierungs-
signale, die durch die Identifizierungssignaler-
fassungseinrichtung (21, 22) erfaßt wurden; und

eine Mobilstation-Funkübertragungseinrich-
tung (25) zum Übertragen der ein optimales
Funkübertragungssystem anzeigenden Infor-
mation, die ein Funkübertragungssystem der
Basisstation darstellt, das das durch die Ent-
scheidungseinrichtung (23) bestimmte Identi-
fizierungssignal überträgt.

3. System nach Anspruch 1, wobei
die Basisstation (1) aufweist:

eine Identifizierungssignalerzeugungseinrich-
tung (3) zum Erzeugen eines Identifizierungs-

signals (A),

eine Verzögerungseinrichtung (27) zum Verzögern des von der Identifizierungssignalerzeugungseinrichtung (3) ausgegebenen Identifizierungssignals (A);

eine Setzeinrichtung (9, 10) zum Setzen verschiedener Pegel für die Sendedaten der mehreren Funkübertragungssysteme (11, 13; 12, 14);

eine Addiereinrichtung (6, 8) zum Addieren der von der Setzeinrichtung (9, 10) ausgegebenen Daten und des Identifizierungssignals (A, Ba) von der Identifizierungssignalerzeugungseinrichtung (3) oder von der Verzögerungseinrichtung (27) und zum Ausgeben der erhaltenen addierten Daten;

eine Basisstation-Funkübertragungseinrichtung (11, 12) zum Übertragen der von der Addiereinrichtung (6, 8) jeweils ausgegebenen addierten Funkdaten; und

eine Basisstation-Funkempfangs- und Extraktionseinrichtung (16, 17) zum Empfangen einer Funkübertragung von der Mobilstation (2) und zum Extrahieren der ein optimales Funkübertragungssystem anzeigenden Information, die eine Übertragung über das durch die Mobilstation (2) bestimmte optimale Funkübertragungssystem darstellt;

wobei die Setzeinrichtung das optimale Funkübertragungssystem durch Setzen der verschiedenen Pegel basierend auf der das optimale Funkübertragungssystem anzeigenden Information auswählt, die durch die Basisstation-Funkempfangs- und Extraktionseinrichtung (16, 17) extrahiert wurde; und

wobei die Mobilstation (2) aufweist:

eine Mobilstation-Funkempfangseinrichtung (19) zum Ausgeben von von der Basisstation (1) empfangenen Daten;

eine Identifizierungssignalerfassungseinrichtung (28) zum Erfassen der mehreren Identifizierungssignale (A, Ba) der mehreren Funkübertragungssysteme (11, 13; 12, 14) von den von der Mobilstation-Funkempfangseinrichtung (19) empfangenen Daten;

eine Entscheidungseinrichtung (23) zum Bestimmen eines der mehreren Identifizierungssignale, die durch die Identifizierungssignalerfassungseinrichtung (28) erfaßt wurden, das einen optimalen Empfangszustand darstellt; und eine Mobilstation-Funkübertragungseinrichtung (25) zum Übertragen der ein optimales Funkübertragungssystem anzeigenden Information, die ein Funkübertragungssystem der Basisstation (1) darstellt, das das durch die Entscheidungseinrichtung (23) bestimmte

Identifizierungssignal überträgt.

4. System nach Anspruch 3, wobei die Identifizierungssignalerfassungseinrichtung (28) aufweist:

eine Identifizierungssignalsucheinrichtung (28) zum Berechnen einer Gleitfunktion zwischen einem Empfangssignal und dem als Referenzsignal dienenden Identifizierungssignal (A) von der Identifizierungssignalerzeugungseinrichtung (3) und zum Bereitstellen eines Verzögerungsprofils, das Feldstärken der Identifizierungssignale bezüglich einer Verzögerungszeit darstellt; und

eine Entscheidungseinrichtung (23) zum Bestimmen der ein optimales Funkübertragungssystem anzeigenden Information, die eines der mehreren Identifizierungssignale darstellt, das die höchste Signalstärke aufweist, vom durch die Identifizierungssignalsucheinrichtung (28) erhaltenen Verzögerungsprofil.

5. System nach einem der Ansprüche 2 bis 4, wobei die Setzeinrichtung (9, 10) mehrere variable Dämpfungseinrichtungen (9, 10) zum variablen Dämpfen der Sendedaten für die jeweiligen Funkübertragungssysteme aufweist.

6. System nach einem der Ansprüche 2 bis 4, wobei die Setzeinrichtung (9, 10) Schalter zum Setzen eines Übertragungszustands oder eines Nicht-Übertragungszustands der Sendedaten für die jeweiligen Funkübertragungssysteme (11, 13; 12, 14) aufweist.

7. System nach einem der Ansprüche 2 bis 6, ferner mit einer Multiplexeinrichtung (5) zum Codieren mehrerer Sendedaten für mehrere Mobilstationen (2) und zum Ausgeben codierter Daten an die Setzeinrichtung (9, 10).

8. System nach Anspruch 7, wobei die Multiplexeinrichtung (5) ein CDMA- (Codemultiplex-Vielfachzugriff) Schema als Multiplexschema verwendet.

9. Basisstation in einem Sendediversitätssystem mit mehreren Funkübertragungssystemen (11, 13; 12, 14) und zum Ausführen einer Diversitätsübertragung von Daten zu einer Mobilstation (2);

wobei die Basisstation (1) eine Einrichtung zum Addieren von Sendedaten und Identifizierungssignalen (A, B; A, Ba), die für die mehreren Funkübertragungssysteme verschieden sind, zum Übertragen von von den mehreren Funkübertragungssystemen (11, 13; 12, 14) erhaltenen Funksignale aufweist; und

dadurch gekennzeichnet, daß die Basisstation ferner eine Einrichtung zum Steuern von Pe-

geln der Sendedaten von den mehreren Funkübertragungssystemen basierend auf einer ein optimales Funkübertragungssystem anzeigenden Information aufweist, die als Funkwelle von der Mobilstation (2) übertragen wird;

wobei die das optimale Funkübertragungssystem anzeigende Information durch die Mobilstation (2) von den mehreren Identifizierungssignalen (A, B; A, Ba) erzeugt wird.

10. Basisstation nach Anspruch 9, wobei die Basisstation (1) aufweist:

eine Identifizierungssignalerzeugungseinrichtung (3, 4) zum Erzeugen der mehreren Typen von Identifizierungssignalen (A, B), die für die mehreren Funkübertragungssysteme (11, 13; 12, 14) verschieden sind;

eine Setzeinrichtung (9, 10) zum Setzen verschiedener Pegel für die Sendedaten der mehreren Funkübertragungssysteme (11, 13; 12, 14);

eine Addiereinrichtung (6, 8) zum Addieren der Identifizierungssignale (A, B) von der Identifizierungssignalerzeugungseinrichtung (3, 4) und der von der Setzeinrichtung (9, 10) ausgegebenen Daten und zum Ausgeben der erhaltenen addierten Daten;

eine Basisstation-Funkübertragungseinrichtung (11, 12) zum Übertragen der von der Addiereinrichtung (6, 8) jeweils ausgegebenen addierten Funkdaten; und

eine Basisstation-Funkempfangs- und Extraktionseinrichtung (16, 17) zum Empfangen einer Funkübertragung von der Mobilstation (2) und zum Extrahieren der ein optimales Funkübertragungssystem anzeigenden Information, die eine Übertragung über das durch die Mobilstation (2) bestimmte optimale Funkübertragungssystem darstellt;

wobei die Setzeinrichtung das optimale Funkübertragungssystem durch Setzen der verschiedenen Pegel basierend auf der das optimale Funkübertragungssystem anzeigenden Information auswählt, die durch die Basisstation-Funkempfangs- und Extraktionseinrichtung (16, 17) extrahiert wurde.

Revendications

1. Système de transmission en diversité comprenant une station de base (1) et une station mobile (2), la station de base comprenant une pluralité de systèmes de transmission radio (11, 13 ; 12, 14) et exécutant une transmission de données en diversité vers ladite station mobile (2)

où ladite station de base (1) comprend des moyens pour additionner des données de transmission et des signaux d'identification (A, B ; A, Ba) différents dans la pluralité de systèmes de transmission radio, afin de transmettre des signaux radio résultants depuis ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14)

et caractérisé en ce qu'il comprend en outre des moyens pour commander des niveaux desdites données de transmission depuis ladite pluralité de systèmes de transmission radio d'après des informations de système de transmission radio optimal, transmises sous la forme d'une onde radio depuis ladite station mobile (2), et

ladite station mobile (2) comprenant des moyens pour déterminer un signal d'identification, représentant un état de réception optimal parmi la pluralité de signaux d'identification (A, B ; A, Ba) détectés parmi les données reçues depuis la pluralité de systèmes de transmission radio (11, 13 ; 12, 14) de ladite station de base (1), et des moyens pour transmettre les informations de système de transmission radio optimal vers ladite station de base (1).

2. Système selon la revendication 1, dans lequel ladite station de base (1) comprend

des moyens de génération de signaux d'identification (3, 4) pour générer la pluralité de types de signaux d'identification (A, B) différents dans la pluralité de systèmes de transmission radio (11, 13 ; 12, 14),

des moyens de réglage (9, 10) pour régler des niveaux différents entre les données de transmission de ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14),

des moyens d'addition (6, 8) pour additionner les signaux d'identification (A, B) issus desdits moyens de génération de signaux d'identification (3, 4) et les données issues desdits moyens de réglage (9, 10), et générer en sortie des données d'addition résultantes,

des moyens de transmission radio de station de base (11, 12) pour transmettre les données d'addition radio respectivement issues desdits moyens d'addition (6, 8), et

des moyens de réception/extraction radio de station de base (16, 17) pour recevoir la transmission radio depuis ladite station mobile (2) et extraire les informations de système de transmission radio optimal, représentant la transmission à travers le système de transmission radio optimal déterminée par ladite station mobile (2),

dans lequel lesdits moyens de réglage sélectionnent ledit système de transmission optimal en réglant lesdits niveaux différents d'après les informations de système de transmission radio optimal extraites par lesdits moyens de réception/extraction radio de station de base (16, 17) ; et

ladite station mobile (2) comprend
des moyens de réception radio de station mobile (19) pour générer en sortie des données reçues depuis ladite station de base (1),

des moyens de détection de signaux d'identification (21, 22) pour détecter la pluralité de signaux d'identification (A, B) différents dans ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14) depuis des données reçues par lesdits moyens de réception radio de station mobile (19),

des moyens de détermination (23) pour déterminer un parmi la pluralité de signaux d'identification détectés par lesdits moyens de détection de signaux d'identification (21, 22) et

des moyens de transmission radio de station mobile (25) pour transmettre les informations de système de transmission radio optimal, représentant un système de transmission radio de ladite station de base qui transmet le signal d'identification déterminé par lesdits moyens de détermination (23).

3. Système selon la revendication 1, dans lequel ladite station de base (1) comprend

des moyens de génération de signaux d'identification (3) pour générer un signal d'identification (A),

des moyens de retard (27) pour retarder le signal d'identification (A) issu desdits moyens de génération de signaux d'identification (3) ;

des moyens de réglage (9, 10) pour régler des niveaux différents entre des données de transmission de ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14),

des moyens d'addition (6, 8) pour additionner des données issues desdits moyens de réglage (9, 10) et le signal d'identification (A, Ba) issu desdits moyens de génération de signaux d'identification (3) ou desdits moyens de retard (27) et générer en sortie des données d'addition résultantes,

des moyens de transmission radio de station de base (11, 12) pour transmettre les données d'addition radio issues respectivement desdits moyens d'addition (6, 8) ; et

des moyens de réception/extraction radio de station de base (16, 17) pour recevoir une transmission radio depuis ladite station mobile (2) et extraire des informations de système de transmission radio optimal, représentant la transmission à travers le système de transmission radio optimal déterminée par ladite station mobile (2),

dans lequel lesdits moyens de réglage sélectionnent ledit système de transmission optimal en réglant lesdits niveaux différents d'après les informations de système de transmission radio optimal extraites par lesdits moyens de réception/extraction radio de station de base (16, 17) ; et

ladite station mobile (2) comprend

des moyens de réception radio de station mobile (19) pour générer en sortie des données reçues depuis ladite station de base (1) ;

des moyens de détection de signaux d'identification (28) pour détecter la pluralité de signaux d'identification (A, Ba) de ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14) parmi les données reçues depuis lesdits moyens de réception radio de station mobile (19) ;

des moyens de détermination (23) pour déterminer un parmi la pluralité de signaux d'identification qui est détecté par lesdits moyens de détection de signaux d'identification (28) et représente un état de réception optimal, et

des moyens de transmission radio de station mobile (25) pour transmettre les informations de système de transmission radio optimal, représentant un système de transmission radio de ladite station de base (1) qui transmet le signal d'identification déterminé par lesdits moyens de détermination (23).

4. Système selon la revendication 3, dans lequel lesdits moyens de détection de signaux d'identification (28) comprennent :

des moyens de recherche de signaux d'identification (28) pour calculer une fonction glissante entre un signal de réception et le signal d'identification (A) servant de référence issu desdits moyens de génération de signaux d'identification (3) et obtenir un profil de retard, représentant des intensités de champs des signaux d'identification en fonction d'un temps de retard ; et

des moyens de détermination (23) pour obtenir les informations de système de transmission radio optimal, représentant un parmi la pluralité de signaux d'identification qui a la force de signal la plus élevée depuis le profil de retard obtenu par lesdits moyens de recherche de signaux d'identification (28).

5. Système selon l'une quelconque des revendications 2 à 4, dans lequel lesdits moyens de réglage (9, 10) comprennent une pluralité de moyens d'atténuation variable (9, 10) pour atténuer de façon variable les données de transmission pour les systèmes de transmission radio respectifs.

6. Système selon l'une quelconque des revendications 2 à 4, dans lequel lesdits moyens de réglage (9, 10) comprennent des commutateurs pour régler la transmission ou la non-transmission des données de transmission pour les systèmes de transmission radio respectifs (11, 13 ; 12, 14).

7. Système selon l'une quelconque des revendica-

tions 2 à 6, comprenant en outre des moyens de multiplexage (5) pour coder une pluralité de données de transmission pour une pluralité de stations mobiles (2) et générer en sortie des données codées vers lesdits moyens de réglage (9, 10).

5

8. Système selon la revendication 7, dans lequel lesdits moyens de multiplexage (5) utilisent une technique CDMA (accès multiples par répartition en code) comme technique de multiplexage.

10

9. Station de base dans un système de transmission en diversité, comprenant une pluralité de systèmes de transmission radio (11, 13 ; 12, 14) et exécutant une transmission de données en diversité vers une station mobile (2),

15

ladite station de base (1) comprenant des moyens pour additionner des données de transmission et des signaux d'identification (A, B ; A, Ba) différents dans la pluralité de systèmes de transmission radio pour transmettre des signaux radio résultants depuis ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14), et

20

caractérisé en ce qu'il comprend en outre des moyens pour commander des niveaux desdites données de transmission issues de ladite pluralité de systèmes de transmission radio, d'après des informations de système de transmission radio optimal transmises sous la forme d'une onde radio depuis ladite station mobile (2), lesdites informations de système de transmission radio optimal étant générées par ladite station mobile (2) à partir de la pluralité de signaux d'identification (A, B ; A, Ba).

25

30

10. Station de base selon la revendication 9, dans laquelle ladite station de base (1) comprend

35

des moyens de génération de signaux d'identification (3, 4) pour générer la pluralité de types de signaux d'identification (A, B) différents dans la pluralité de systèmes de transmission radio (11, 13 ; 12, 14),

40

des moyens de réglage (9, 10) pour régler des niveaux différents entre des données de transmission de ladite pluralité de systèmes de transmission radio (11, 13 ; 12, 14),

45

des moyens d'addition (6, 8) pour additionner les signaux d'identification (A, B) depuis lesdits moyens de génération de signaux d'identification (3, 4) et les données issues desdits moyens de réglage (9, 10) et générer en sortie des données d'addition résultantes,

50

des moyens de transmission radio de station de base (11, 12) pour transmettre les données d'addition radio issues respectivement desdits moyens d'addition (6, 8), et

55

des moyens de réception/extraction radio de station de base (16, 17) pour recevoir une transmission radio depuis ladite station mobile (2) et extraire

les informations de système de transmission radio optimal, représentant la transmission à travers le système de transmission radio optimal déterminée par ladite station mobile (2),

dans lequel lesdits moyens de réglage sélectionnent ledit système de transmission radio optimal en réglant lesdits niveaux différents d'après les informations de système de transmission radio optimal extraites par lesdits moyens de réception/extraction radio de station de base (16, 17).
